Reminder from Last Lecture

- Convert the image into binary form
 - Thresholding
- Clean up the thresholded image
 - Morphological operators
- Extract individual objects
 - Connected Components Labeling
- Describe the objects
 - Region properties

B. Leibe Image Source: D. Kim et al., Cytometry 35(1), 1999

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Region Properties

- From the previous steps, we can obtain separated objects.
- Some useful features can be extracted once we have connected components, including
 - Area
 - Centroid
 - Extremal points, bounding box
 - Circularity
 - Spatial moments

B. Leibe

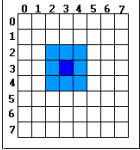

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Area and Centroid

- We denote the set of pixels in a region by R
- Assuming square pixels, we obtain
 - Area:
$$A = \sum_{(x,y) \in R} 1$$
 - Centroid:
$$\bar{x} = \frac{1}{A} \sum_{(x,y) \in R} x$$

$$\bar{y} = \frac{1}{A} \sum_{(x,y) \in R} y$$

Source: Shapiro & Stockman B. Leibe

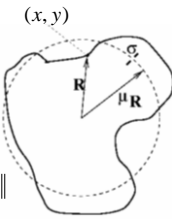

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Circularity

- Measure the deviation from a perfect circle
 - Circularity:
$$C = \frac{\mu_R}{\sigma_R}$$

where μ_R and σ_R^2 are the mean and variance of the distance from the centroid of the shape to the boundary pixels (x_k, y_k) .

- Mean radial distance:
$$\mu_R = \frac{1}{K} \sum_{k=0}^{K-1} \|(x_k, y_k) - (\bar{x}, \bar{y})\|$$
- Variance of radial distance:
$$\sigma_R^2 = \frac{1}{K} \sum_{k=0}^{K-1} \left[\|(x_k, y_k) - (\bar{x}, \bar{y})\| - \mu_R \right]^2$$

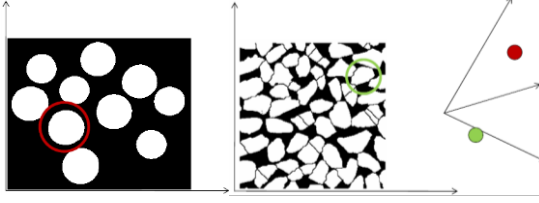

Source: Shapiro & Stockman B. Leibe

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Invariant Descriptors

- Often, we want features independent of location, orientation, scale.

$[a_1, a_2, a_3, \dots]$ $[b_1, b_2, b_3, \dots]$ Feature space distance

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Central Moments

- S is a subset of pixels (region).
- Central (j,k) th moment defined as:

$$\mu_{jk} = \sum_{(x,y) \in S} (x - \bar{x})^j (y - \bar{y})^k$$
- Invariant to translation of S .
- Interpretation:
 - 0th central moment: *area*
 - 2nd central moment: *variance*
 - 3rd central moment: *skewness*
 - 4th central moment: *kurtosis*

Computer Vision WS 16/17 8

Slide credit: Kristen Grauman B. Leibe

RWTH AACHEN UNIVERSITY

Moment Invariants (“Hu Moments”)

- Normalized central moments

$$\eta_{pq} = \frac{\mu_{pq}}{\mu_{00}^\gamma}, \quad \gamma = \frac{p+q}{2} + 1$$
- From those, a set of *invariant moments* can be defined for object description.

$$\phi_1 = \eta_{20} + \eta_{02}$$

$$\phi_2 = (\eta_{20} - \eta_{02})^2 + 4\eta_{11}^2$$

$$\phi_3 = (\eta_{30} - 3\eta_{12})^2 + (3\eta_{21} - \eta_{03})^2$$

$$\phi_4 = (\eta_{30} + \eta_{12})^2 + (\eta_{21} + \eta_{03})^2$$
- Robust to translation, rotation & scaling, but don't expect wonders (still summary statistics).

Computer Vision WS 16/17 9

B. Leibe

RWTH AACHEN UNIVERSITY

Moment Invariants

$$\phi_5 = (\eta_{30} - 3\eta_{12})(\eta_{30} + \eta_{12})[(\eta_{30} + \eta_{12})^2 - 3(\eta_{21} + \eta_{03})^2] + (3\eta_{21} - \eta_{03})(\eta_{21} + \eta_{03})[3(\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2]$$

$$\phi_6 = (\eta_{20} - \eta_{02})[(\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2] + 4\eta_{11}(\eta_{30} + \eta_{12})(\eta_{21} + \eta_{03})$$

$$\phi_7 = (3\eta_{21} - \eta_{03})(\eta_{30} + \eta_{12})[(\eta_{30} + \eta_{12})^2 - 3(\eta_{21} + \eta_{03})^2] + (3\eta_{12} - \eta_{30})(\eta_{21} + \eta_{03})[3(\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2]$$

Often better to use $\log_{10}(\phi_i)$ instead of ϕ_i directly...

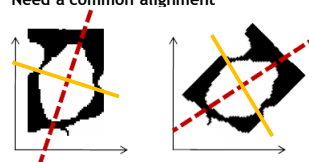

Computer Vision WS 16/17 10

B. Leibe

RWTH AACHEN UNIVERSITY

Axis of Least Second Moment

- Invariance to orientation?
 - Need a common alignment

Axis for which the squared distance to 2D object points is **minimized** (maximized).

- Compute Eigenvectors of 2nd moment matrix (Matlab: eig(A))

$$\begin{bmatrix} \mu_{20} & \mu_{11} \\ \mu_{11} & \mu_{02} \end{bmatrix} = VDV^T = \begin{bmatrix} v_{11} & v_{12} \\ v_{22} & v_{22} \end{bmatrix} \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix} \begin{bmatrix} v_{11} & v_{12} \\ v_{22} & v_{22} \end{bmatrix}^T$$

Computer Vision WS 16/17 11

RWTH AACHEN UNIVERSITY

Summary: Binary Image Processing

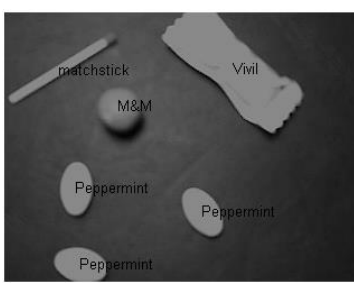

- Pros
 - Fast to compute, easy to store
 - Simple processing techniques
 - Can be very useful for constrained scenarios
- Cons
 - Hard to get “clean” silhouettes
 - Noise is common in realistic scenarios
 - Can be too coarse a representation
 - Cannot deal with 3D changes

Computer Vision WS 16/17 12

You Can Do It At Home...

Accessing a webcam in Matlab:

```
function out = webcam
% uses "Image Acquisition Toolbox,"
adaptorName = 'winvideo';
vidFormat = 'I420_320x240';
vidObj1= videoinput(adaptorName, 1, vidFormat);
set(vidObj1, 'ReturnedColorSpace', 'rgb');
set(vidObj1, 'FramesPerTrigger', 1);
out = vidObj1 ;

cam = webcam();
img=getsnapshot(cam);
```

Course Outline

- Image Processing Basics
 - Image Formation
 - Binary Image Processing
 - Linear Filters
 - Edge & Structure Extraction
 - Color
- Segmentation
- Local Features & Matching
- Object Recognition and Categorization
- 3D Reconstruction
- Motion and Tracking

Computer Vision WS 16/17

B. Leibe

15

Motivation

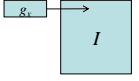

- Noise reduction/image restoration
 
- Structure extraction
 

Computer Vision WS 16/17

B. Leibe

16

Topics of This Lecture

- Linear filters
 - What are they? How are they applied?
 - Application: smoothing
 - Gaussian filter
 - What does it mean to filter an image?
- Nonlinear Filters
 - Median filter
- Multi-Scale representations
 - How to properly rescale an image?
- Filters as templates
 - Correlation as template matching

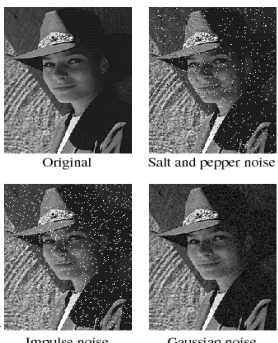

Computer Vision WS 16/17

B. Leibe

17

Common Types of Noise

- Salt & pepper noise
 - Random occurrences of black and white pixels
- Impulse noise
 - Random occurrences of white pixels
- Gaussian noise
 - Variations in intensity drawn from a Gaussian ("Normal") distribution.
- Basic Assumption
 - Noise is i.i.d. (independent & identically distributed)

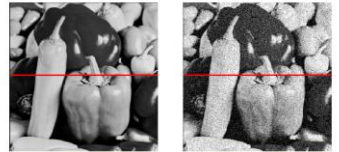

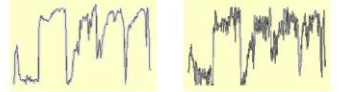

Computer Vision WS 16/17

B. Leibe

Source: Steve Seitz

18

Gaussian Noise

Ideal Image $f(x,y)$ Noise process $\eta(x,y)$ Gaussian i.i.d. ("white") noise: $\eta(x,y) \sim \mathcal{N}(\mu, \sigma)$

```
>> noise = randn(size(im)).*sigma;
>> output = im + noise;
```

19

First Attempt at a Solution

- Assumptions:
 - Expect pixels to be like their neighbors
 - Expect noise processes to be independent from pixel to pixel ("i.i.d. = independent, identically distributed")
- Let's try to replace each pixel with an average of all the values in its neighborhood...

Moving Average in 2D

$$F[x, y]$$

$$G[x, y]$$

Moving Average in 2D

$$F[x, y]$$

$$G[x, y]$$

Moving Average in 2D

Computer Vision WS 16/17

Correlation Filtering

- Say the averaging window size is $2k+1 \times 2k+1$:

$$G[i, j] = \frac{1}{(2k+1)^2} \sum_{u=-k}^k \sum_{v=-k}^k F[i+u, j+v]$$

Attribute uniform weight to each pixel Loop over all pixels in neighborhood around image pixel $F[i, j]$
- Now generalize to allow different weights depending on neighboring pixel's relative position:

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i+u, j+v]$$

Non-uniform weights

Slide credit: Kristen Grauman B. Leibe 27

Computer Vision WS 16/17

Correlation Filtering

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i+u, j+v]$$

- This is called **cross-correlation**, denoted $G = H \otimes F$
- Filtering an image
 - Replace each pixel by a weighted combination of its neighbors.
 - The filter "kernel" or "mask" is the prescription for the weights in the linear combination.

Slide credit: Kristen Grauman B. Leibe 28

Computer Vision WS 16/17

Convolution

- Convolution:
 - Flip the filter in both dimensions (bottom to top, right to left)
 - Then apply cross-correlation

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i-u, j-v]$$

$G = H \star F$

↑
Notation for convolution operator

H

F

(N,N)

Slide credit: Kristen Grauman B. Leibe 29

Computer Vision WS 16/17

Correlation vs. Convolution

- Correlation

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i+u, j+v]$$

Matlab: `filter2`
`imfilter`

$$G = H \otimes F$$
- Convolution

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i-u, j-v]$$

Matlab: `conv2`

$$G = H \star F$$
- Note
 - If $H[-u, -v] = H[u, v]$, then correlation = convolution.

Note the difference!

Slide credit: Kristen Grauman B. Leibe 30

Computer Vision WS 16/17

Shift Invariant Linear System

- Shift invariant:
 - Operator behaves the same everywhere, i.e. the value of the output depends on the pattern in the image neighborhood, not the position of the neighborhood.
- Linear:
 - Superposition: $h \star (f_1 + f_2) = (h \star f_1) + (h \star f_2)$
 - Scaling: $h \star (kf) = k(h \star f)$

Slide credit: Kristen Grauman B. Leibe 31

RWTH AACHEN UNIVERSITY

Properties of Convolution

- Linear & shift invariant
- Commutative: $f \star g = g \star f$
- Associative: $(f \star g) \star h = f \star (g \star h)$
 - Often apply several filters in sequence: $((a \star b_1) \star b_2) \star b_3$
 - This is equivalent to applying one filter: $a \star (b_1 \star b_2 \star b_3)$
- Identity: $f \star e = f$
 - for unit impulse $e = [\dots, 0, 0, 1, 0, 0, \dots]$.
- Differentiation: $\frac{\partial}{\partial x}(f \star g) = \frac{\partial f}{\partial x} \star g$

32

RWTH AACHEN UNIVERSITY

Averaging Filter

- What values belong in the kernel $H[u, v]$ for the moving average example?

$F[x, y]$

\otimes

$H[u, v]$

$=$

$G[x, y]$

$\frac{1}{9}$

\otimes

“box filter”

$G = H \otimes F$

36

RWTH AACHEN UNIVERSITY

Gaussian Smoothing

- Gaussian kernel

$$G_\sigma = \frac{1}{2\pi\sigma^2} e^{-\frac{(x^2+y^2)}{2\sigma^2}}$$
- Rotationally symmetric
- Weights nearby pixels more than distant ones
 - This makes sense as ‘probabilistic’ inference about the signal
- A Gaussian gives a good model of a fuzzy blob

37

Gaussian Smoothing

- What parameters matter here?
- **Variance** σ of Gaussian
 - > Determines extent of smoothing

Slide credit: Kristen Grauman B. Leibe 38

Gaussian Smoothing

- What parameters matter here?
- **Size** of kernel or mask
 - > Gaussian function has infinite support, but discrete filters use finite kernels

- > Rule of thumb: set filter half-width to about 3σ !

Slide credit: Kristen Grauman B. Leibe 39

Gaussian Smoothing in Matlab

```

>> hsize = 10;
>> sigma = 5;
>> h = fspecial('gaussian' hsize, sigma);

>> mesh(h);
>> imagesc(h);

>> outim = imfilter(im, h);
>> imshow(outim);

```

More noise →

Slide credit: Kristen Grauman B. Leibe Image Source: Forsyth & Ponce 41

Efficient Implementation

- Both, the BOX filter and the Gaussian filter are separable:
 - > First convolve each row with a 1D filter

$$g(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp(-x^2 / (2\sigma^2))$$
 - > Then convolve each column with a 1D filter

$$g(y) = \frac{1}{\sqrt{2\pi}\sigma} \exp(-y^2 / (2\sigma^2))$$
- Remember:
 - > Convolution is linear - associative and commutative

$$g_x * g_y * I = g_x * (g_y * I) = (g_x * g_y) * I$$

Slide credit: Bernt Schiele B. Leibe 42

Filtering: Boundary Issues

- What is the size of the output?
- MATLAB: `filter2(g, f, shape)`
 - > *shape* = 'full': output size is sum of sizes of f and g
 - > *shape* = 'same': output size is same as f
 - > *shape* = 'valid': output size is difference of sizes of f and g

Slide credit: Svetlana Lazebnik B. Leibe 43

Computer Vision WS 16/17

Filtering: Boundary Issues

- How should the filter behave near the image boundary?
 - The filter window falls off the edge of the image
 - Need to extrapolate
 - Methods:
 - Clip filter (black)
 - Wrap around
 - Copy edge
 - Reflect across edge

B. Leibe 44

RWTH AACHEN UNIVERSITY

Duality

- The better a function is localized in one domain, the worse it is localized in the other.

- This is true for any function

53

Image Source: S. Chentsov

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Effect of Convolution

- Convoluting two functions in the image domain corresponds to taking the product of their transformed versions in the frequency domain.

$$f \star g \rightarrow \mathcal{F} \cdot \mathcal{G}$$

- This gives us a tool to manipulate image spectra.
 - A filter attenuates or enhances certain frequencies through this effect.

54

Image Source: S. Chentsov

Computer Vision WS 16/17

RWTH AACHEN UNIVERSITY

Effect of Filtering

- Noise introduces high frequencies. To remove them, we want to apply a “low-pass” filter.

- The ideal filter shape in the frequency domain would be a box. But this transfers to a spatial sinc, which has infinite spatial support.

- A compact spatial box filter transfers to a frequency sinc, which creates artifacts.

- A Gaussian has compact support in both domains. This makes it a convenient choice for a low-pass filter.

Non-Linear Filters: Median Filter

- **Basic idea**
 - Replace each pixel by the median of its neighbors.

10	15	20
23	90	27
33	31	30

Median value →

↓ Sort

10	15	20	27	30	31	33	90
----	----	----	----	----	----	----	----

↓ Replace

10	15	20
23	27	27
33	31	30

- **Properties**
 - Doesn't introduce new pixel values
 - Removes spikes: good for impulse, salt & pepper noise

- RWTH AACHEN UNIVERSITY
- ### Summary: Gaussian Pyramid
- Construction: create each level from previous one
 - Smooth and sample
 - Smooth with Gaussians, in part because
 - a Gaussian * Gaussian = another Gaussian
 - $G(\sigma_1) * G(\sigma_2) = G(\sqrt{\sigma_1^2 + \sigma_2^2})$
 - Gaussians are low-pass filters, so the representation is redundant once smoothing has been performed.
 - ⇒ There is no need to store smoothed images at the full original resolution.

Correlation as Template Matching

- Think of filters as a dot product of the filter vector with the image region
 - Now measure the angle between the vectors

$$a \cdot b = |a| |b| \cos \theta \quad \cos \theta = \frac{a \cdot b}{|a| |b|}$$
 - Angle (similarity) between vectors can be measured by normalizing length of each vector to 1.

Template Image region Vector interpretation

B. Leibe

87

Computer Vision WS 16/17

Summary: Mask Properties

- Smoothing**
 - Values positive
 - Sum to 1 \Rightarrow constant regions same as input
 - Amount of smoothing proportional to mask size
 - Remove "high-frequency" components; "low-pass" filter
- Filters act as templates**
 - Highest response for regions that "look the most like the filter"
 - Dot product as correlation

Slide credit: Kristen Grauman B. Leibe

Computer Vision WS 16/17

Summary Linear Filters

- Linear filtering:**
 - Form a new image whose pixels are a weighted sum of original pixel values
- Properties**
 - Output is a shift-invariant function of the input (same at each image location)

Examples:

- Smoothing with a box filter
- Smoothing with a Gaussian
- Finding a derivative
- Searching for a template

Pyramid representations

- Important for describing and searching an image at all scales

B. Leibe

89

Computer Vision WS 16/17

References and Further Reading

- Background information on linear filters and their connection with the Fourier transform can be found in Chapters 7 and 8 of
